Abstract. Imposing a strong condition on the linear order of shellable complexes, we introduce strong shellability. Basic properties, including the existence of dimension-decreasing strong shelling orders, are developed with respect to nonpure strongly shellable complexes. Meanwhile, pure strongly shellable complexes can be characterized by the corresponding codimension one graphs. In addition, we show that the facet ideals of pure strongly shellable complexes have linear quotients.

1. Introduction

Recall that a simplicial complex $\Delta$ on a vertex set $V(\Delta) = V$ is a finite subset of $2^V$, such that $A \in \Delta$ and $B \subseteq A$ implies $B \in \Delta$. The set $A$ is called a face if $A \in \Delta$, and called a facet if $A$ is a maximal face with respect to inclusion. The set of facets of $\Delta$ will be denoted by $\mathcal{F}(\Delta)$. Typically, for the complexes considered here, the vertex set is the set $[n] := \{1, 2, \ldots, n\}$ for some $n \in \mathbb{Z}_+$. When $\mathcal{F}(\Delta) = \{F_1, \ldots, F_m\}$, we write $\Delta = \langle F_1, \ldots, F_m \rangle$. In particular, if $\Delta$ has a unique facet $F$, then $\Delta$ is called a simplex. The dimension of a face $A$, denoted by $\dim(A)$, is $|A| - 1$. The dimension of a complex $\Delta$, denoted by $\dim(\Delta)$, is the maximum dimension of its faces. The complex $\Delta$ is called pure if all the facets of $\Delta$ have the same dimension; otherwise, it will be called nonpure.

Recall that a $d$-dimensional pure complex $\Delta$ on $[n]$ is called shellable if there exists a shelling order on its facet set $\mathcal{F}(\Delta)$, say $F_1, \ldots, F_m$, such that the subcomplex $\langle F_1, \ldots, F_{k-1} \rangle \cap \langle F_k \rangle$ is pure of dimension $d-1$ for each $2 \leq k \leq m$. As pointed out in [16], “Shellability is a simple but powerful tool for proving the Cohen-Macaulay property, and almost all Cohen-Macaulay complexes arising ‘in nature’ turn out to be shellable. Moreover, a number of invariants associated with Cohen-Macaulay complexes can be described more explicitly or computed more easily in the shellable case.” Shellability was later generalized to nonpure complexes by Björner and Wachs [3, 4]. Matroid complexes, shifted complexes and vertex decomposable complexes are all known to be important shellable complexes.

In the present paper, we will impose a stronger requirement on the linear order of shellability, hence end up with a new kind of complex, which will be called as strongly shellable. Its basic properties will be discussed in Section 2. Using restriction maps, Björner and Wachs [3] showed that any nonpure shellable complex has a dimension-decreasing shelling order. Using a different technique, we will establish a similar result for strongly shellable complexes; see Theorem 2.8 and its corollary.

In Section 3, we introduce the codimension one graph of complexes. We will investigate the strong shellability from this point of view. In Section 4, we focus on pure strongly shellable complexes and provide several equivalent characterizations, in particular, using its codimension one graph. It is well-known that if $\Delta$ is a shellable complex, then the Stanley-Reisner ideal of its dual complex $\Delta^\vee$ has linear quotients. If in addition $\Delta$ is strongly shellable, we will show that the facet ideal of $\Delta$ also has linear quotients. This property will be the main topic when we study the chordal (hyper)-graphs in the sequel paper [5].

As applications, we will consider strongly shellable posets in Section 5. In section 6, we will discuss the relationship between strongly shellable complexes and other shellable complexes in the pure case. In the final section, we notice that strongly shellable complexes can be characterized by strong h-assignments, an easy generalization of a result of Moriyama [12]. This provides a relatively fast algorithm for checking strong shellability.

2. STRONGLY SHELLABLE COMPLEXES, GENERAL CASE

Shellability of general complexes were introduced by Björner and Wachs in [3, 4].

**Definition 2.1.** A complex $\Delta$ is shellable if its facets can be ordered $F_1, F_2, \ldots, F_t$ such that the subcomplex $\langle F_1, \ldots, F_{k-1} \rangle \cap \langle F_k \rangle$ is pure of dimension $\dim(F_k) - 1$ for all $k = 2, \ldots, t$. Such an ordering of facets is called a shelling order of $\Delta$.

Sometimes, one may refer to shellable complexes as semipure shellable or nonpure shellable to emphasize that the complexes are not necessarily pure. Related to this concept, we will impose additional requirement on the above linear order as follows.

**Definition 2.2.** A complex $\Delta$ is called strongly shellable if its facets can be ordered $F_1, F_2, \cdots, F_t$ such that for every $i$ and $j$ with $1 \leq i < j \leq t$, there exists a $k$ with $1 \leq k < j$, such that:

1. $|F_j \setminus F_k| = 1$,
2. $F_j \setminus F_k \subseteq F_i \setminus F_k$, and
3. $F_k \setminus F_j \subseteq F_i$.

Such an ordering of facets will be called a strong shelling order of $\Delta$, or more specifically, a strong shelling order on $\mathcal{F}(\Delta)$.
Note that a complex $\Delta$ is shellable if and only if it satisfies the conditions (1) and (2) of Definition 2.2 by [3, Lemma 2.3]. Hence, for a simplicial complex, strong shellability is indeed stronger than shellability.

**Remark 2.3.** It is easy to see that the conditions (1), (2) and (3) of Definition 2.2 are equivalent to

\begin{align*}
(1)' &\quad \dim(F_j) = \dim(F_j \cap F_k) + 1, \\
(2)' &\quad F_i \cap F_j \subseteq F_k, \text{ and} \\
(3)' &\quad F_k \subseteq F_i \cup F_j
\end{align*}

respectively. In particular, we will always have $\dim(F_j) \leq \dim(F_k)$. It will be helpful to think of the $F_i, F_j$ and $F_k$ in Definition 2.2 as depicted in Figure 1, namely, we may assume that $F_i = P_1 \cup P_2 \cup P_3$, $F_k = P_2 \cup P_3 \cup P_4$, $F_j = P_3 \cup P_4 \cup P_5$ with $|P_5| = 1$. Here, by $\sqcup$, we mean disjoint union. With this figure in mind, we will be able to see, for instance, that $|F_j \setminus F_i| = |F_k \setminus F_i| + 1$.

![Figure 1](image)

Taking advantage of the restriction map, Björner and Wachs [3, Rearrangement lemma 2.6] showed that any shelling order of a nonpure shellable complex can be rearranged to be a shelling order with decreasing dimensions. In the following, we will establish a similar result with respect to strong shellability.

**Lemma 2.4.** Let $\Delta$ be a strongly shellable complex. Then for each pair of facets $F_1$ and $F_2$ with $\dim(F_1) < \dim(F_2)$, there exists a facet $G$, such that $\dim(F_1) = \dim(F_1 \cap G) + 1$ and $F_1 \cap F_2 \subseteq G \subseteq F_1 \cup F_2$.

**Proof.** Let $G_1, G_2, \ldots, G_t$ be a strong shelling order on $\mathcal{F}(\Delta)$. Assume that $F_1 = G_{i_1}$ and $F_2 = G_{i_2}$. We claim that one can find suitable $G = G_i$, with $i < \max(i_1, i_2)$, satisfying the requirement. We establish this claim by induction on $t$. When $t = 2$, this is easy. Thus, we may assume that $t \geq 3$.

If $i_1 > i_2$, the existence of $G$ follows directly from Remark 2.3. Thus, we may assume that $i_1 < i_2$. Since $G_1, G_2, \ldots, G_t$ is a strong shelling order, by Remark 2.3, there exists some $i_3 < i_2$ such that $G_{i_1} \cap G_{i_2} \subseteq G_{i_3} \subseteq G_{i_1} \cup G_{i_2}$. Therefore,

\begin{equation}
G_{i_1} \cap G_{i_2} \subseteq G_{i_1} \cap G_{i_3} \quad \text{and} \quad G_{i_1} \cup G_{i_3} \subseteq G_{i_1} \cup G_{i_2}.
\end{equation}

As $i_1, i_3 < i_2 \leq t$ and $G_1, G_2, \ldots, G_{i_2-1}$ forms a strong shelling order, by induction, we can find $G = G_i$ with $i < \max(i_1, i_3)$ such that

\begin{equation}
\dim(G_{i_1}) = \dim(G_{i_1} \cap G) + 1 \quad \text{and} \quad G_{i_1} \cap G_{i_3} \subseteq G \subseteq G_{i_1} \cup G_{i_3}.
\end{equation}

Combining (1) and (2), we see that the claim works. \qed

Let $\succ: F_1, \ldots, F_t$ be a linear order on the facet set of $\Delta$, i.e., $F_i \succ F_j$ if and only $i < j$. One can define an *induced dimension-related order* $\succ$ on $\mathcal{F}(\Delta)$ as follows: $F \succ G$ if and only if
(1) \( \dim(F) > \dim(G) \), or
(2) \( \dim(F) = \dim(G) \) and \( F > G \).

For a given \( F \in \mathcal{F}(\Delta) \), we will write \( \text{Ini}_{\succ}(F) := \{ G \in \mathcal{F}(\Delta) \mid G \succ F \} \) for the initial interval with respect to \( \succ \) and \( F \).

The following result follows easily from Definition 2.2 and Remark 2.3.

**Lemma 2.5.** Let \( \Delta \) be a strongly shellable complex with a strong shelling order \( \succ \). Then for each facet \( F \), the restrictions of \( \succ \) on both \( \text{Ini}_{\succ}(F) \) and \( \text{Ini}_{\succ}(F) \) are also strong shelling orders of the corresponding subcomplexes.

Let \( \succ : F_1, \ldots, F_t \) be a linear order on \( \mathcal{F}(\Delta) \). Thus, the induced dimension-related order \( \succ \) is fixed. If we are given another linear order \( \succ' \) on \( \mathcal{F}(\Delta) \), we will call \( (F_i, F_j) \) a relative inverse pair with respect to \( \succ \), if \( F_i \succ F_j \) and \( F_j \succ' F_i \). Denote by \( \text{Inv}_{\succ}(\succ') \) the set of relative inverse pairs with respect to \( \succ \). Obviously, one can recover the linear order \( \succ \) from \( \succ \) by switching the pairs of facets in \( \text{Inv}_{\succ}(\succ') \).

We will simply write \( \text{Inv}_{\succ}(\succ) \) as \( \text{Inv}(\succ) \). An ordered pair \( (F_i, F_j) \in \text{Inv}(\succ) \) precisely when \( j < i \) and \( \dim(F_j) < \dim(F_i) \).

**Lemma 2.6.** Let \( \succ \) and \( \succ' \) be two linear orders on \( \mathcal{F}(\Delta) \). If \( \text{Inv}_{\succ}(\succ') \subseteq \text{Inv}(\succ) \), then the induced dimension-related orders \( \succ \) and \( \succ' \) coincide.

**Proof.** Let \( F_i \) and \( F_j \) be two distinct facets. When \( \dim(F_i) > \dim(F_j) \), we have both \( F_i \succ F_j \) and \( F_j \succ F_i \). Therefore, we may assume that \( \dim(F_i) = \dim(F_j) \) and \( F_i \succeq F_j \). Hence, \( F_i \succ F_j \). Note that \( (F_i, F_j) \notin \text{Inv}(\succ) \). It follows from the condition \( \text{Inv}_{\succ}(\succ') \subseteq \text{Inv}(\succ) \) that \( (F_i, F_j) \notin \text{Inv}_{\succ}(\succ') \). But \( F_i \succ F_j \). This simply means that \( F_i \succ' F_j \) and in turn \( F_i \succ F_j \).

**Remark 2.7.** If \( (F_i, F_j) \in \text{Inv}(\succ) \), then \( j < i \) with \( \dim(F_j) < \dim(F_i) \). In this case, we will be able to find a \( k \) with \( j < k < i \) such that \( \dim(F_k) < \dim(F_{k+1}) \). Now \( (F_{k+1}, F_k) \in \text{Inv}(\succ) \). We can modify \( \succ \) by only switching the relation between \( F_k \) and \( F_{k+1} \) and end up with \( \succ' \). Then, \( \succ' \) is indeed a linear order with \( \text{Inv}_{\succ}(\succ') \subseteq \text{Inv}(\succ) \) and \( \text{Inv}(\succ') = \{ (F_{k+1}, F_k) \} \).

**Theorem 2.8** (Rearrangement). Let \( \Delta \) be a nonpure strongly shellable complex with a strong shelling order \( \succ \). Then any linear order \( \succ' \) on \( \mathcal{F}(\Delta) \) is also a strong shelling order, provided that \( \text{Inv}_{\succ}(\succ') \subseteq \text{Inv}(\succ) \).

**Proof.** Assume that \( \succ : F_1, F_2, \ldots, F_t \) gives the strong shelling order on \( \mathcal{F}(\Delta) \). Let \( \succ' \) be another linear order with \( \text{Inv}_{\succ}(\succ') \subseteq \text{Inv}(\succ) \). We may assume that this containment is strict, for otherwise, \( \succ \) coincides with \( \succ' \). By Lemma 2.6 and Remark 2.7, it suffices to consider the case when

\[
\text{Inv}(\succ) \setminus \text{Inv}_{\succ}(\succ') = \{ (F_{i+1}, F_i) \}.
\]

Whence, for arbitrary distinct \( k_1, k_2 \in [t] \), if \( \{ k_1, k_2 \} \neq \{ i, i+1 \} \), then \( F_{k_1} \succ F_{k_2} \) if and only if \( F_{k_1} \succ' F_{k_2} \). On the other hand, \( \dim(F_i) < \dim(F_{i+1}) \) and \( F_{i+1} \succ' F_i \).

Note that the restriction

\[
\ succ_{\text{Ini}_{\succ}(F_i)} : F_1, \cdots, F_i, F_{i+1}
\]

is a strong shelling order of \( \Delta' := \langle F_1, \ldots, F_{i+1} \rangle \) by Lemma 2.5. We claim that the restriction

\[
(\succ')_{\text{Ini}_{\succ}(F_i)} : F_1, \cdots, F_{i-1}, F_{i+1}, F_i
\]
Let \( \Delta \) be a complex with the facet set \( \{ \{1, 2, 3\}, \{2, 3, 4\}, \{3, 4, 5\}, \{4, 5, 6\} \} \).

It is direct to check that \( \Delta \) is strongly shellable, but
\[
\Delta^{(1)} = \Delta^{[1]} = \langle \{1, 2\}, \{2, 3\}, \{1, 3\}, \{2, 4\}, \{3, 4\}, \{3, 5\}, \{4, 5\}, \{4, 6\}, \{5, 6\} \rangle
\]
is not strongly shellable. Actually, using the terminology introduced in the next section, we have
\[
\text{dis}_\Delta(\{1, 2\}, \{5, 6\}) = 2,
\]
and
\[
\text{dis}_{\Gamma(\Delta)}(\{1, 2\}, \{5, 6\}) = 3.
\]
Thus, by Theorem 3.11, the skeleton \( \Delta^{[1]} \) is not strongly shellable.

For a complex \( \Delta \), we denote by \( \text{pure}_k(\Delta) \) the pure complex generated by the \( k \)-dimensional facets of \( \Delta \). Generally speaking, \( \text{pure}_k(\Delta) \) may not necessarily be strongly shellable even though \( \Delta \) is. For example, if \( \Delta = \langle \{1245\}, \{123\}, \{456\} \rangle \), it is easy to check that \( \Delta \) is strongly shellable, while \( \text{pure}_2(\Delta) = \langle \{123\}, \{456\} \rangle \) is not. However, in the special case when \( k = 1 \), the following result holds:

**Proposition 2.12.** Let \( \Delta \) be a strongly shellable complex of positive dimension. Then \( \text{pure}_1(\Delta) \) is also strongly shellable.

**Proof.** Assume that \( F_1, \ldots, F_t \) is a strong shelling order on \( \mathcal{F}(\Delta) \), with \( \dim(F_i) \geq \dim(F_j) \) whenever \( i < j \). We may assume that \( \text{pure}_1(\Delta) = \langle F_{s+1}, \ldots, F_t \rangle \). For each pair \( F_i \) and \( F_j \) with \( s + 1 \leq i < j \leq t \), there exists a \( k \) with \( 1 \leq k < t \), such that \( F_k \subseteq F_i \cup F_j \). Notice that \( \dim(F_k) \geq \dim(F_j) = \dim(F_i) = 1 \). If \( \dim(F_k) \geq 2 \), this will force \( F_i \subseteq F_k \) or \( F_j \subseteq F_k \). Thus, we have indeed \( \dim(F_k) = 1 \), and \( F_k \in \text{pure}_1(\Delta) \). This shows that \( F_{s+1}, \ldots, F_t \) is a strong shelling order of \( \text{pure}_1(\Delta) \). \( \square \)
The above result hints that one-dimensional pure strongly shellable complexes are very special. In our next paper [5], we will show that they are indeed the complements of chordal graphs.

Recall that for a simplicial complex $\Delta$, the link of a face $A \in \Delta$ is defined as
\[
\text{link}_\Delta(A) := \{ B \in \Delta \mid B \cup A \in \Delta, B \cap A = \emptyset \}.
\]

When $A = \{ x \}$, we will simply write it as $\text{link}_\Delta(x)$.

On the other hand, for a subset $W \subseteq V(\Delta)$, the restriction of $\Delta$ on $W$ is the subcomplex
\[
\Delta_W := \{ F \in \Delta : F \subseteq W \}.
\]

The restriction is sometimes denoted by $\Delta[W]$ as well. For a vertex $x \in V(\Delta)$, we will usually write $\Delta_{|V(\Delta) \setminus x}$ as $\Delta \setminus x$.

**Proposition 2.13.** Let $\Delta$ be a strongly shellable complex. Then $\text{link}_\Delta(A)$ is also strongly shellable for any $A \in \Delta$.

**Proof.** Assume that $>$ is a strong shelling order on $\mathcal{F}(\Delta)$. It induces a linear order $>^\prime$ on $\mathcal{F}(\text{link}_\Delta(A)) = \{ F \setminus A \mid A \subseteq F \in \mathcal{F}(\Delta) \}$:
\[
(F^\prime >^\prime G^\prime) \text{ if and only if } (F^\prime \cup A) > (G^\prime \cup A) \text{ in } \mathcal{F}(\Delta).
\]

Now, take arbitrary pair $F_i^\prime >^\prime F_j^\prime$ in $\mathcal{F}(\text{link}_\Delta(A))$. Equivalently, $(F_i^\prime \cup A) > (F_j^\prime \cup A)$ in $\mathcal{F}(\Delta)$.

Hence, there exists some $F_k \in \mathcal{F}(\Delta)$ such that $F_k > (F_j^\prime \cup A)$ and
\[
|(F_j^\prime \cup A) \setminus F_k| = 1 \text{ and } (F_i^\prime \cup A) \cap (F_j^\prime \cup A) \subseteq F_k \subseteq (F_i^\prime \cup A) \cup (F_j^\prime \cup A).
\]

Obviously, $A \subseteq F_k$. So, we can find $F_{k}^\prime := F_k \setminus A \in \mathcal{F}(\text{link}_\Delta(A))$ such that $F_{k}^\prime >^\prime F_k$ with
\[
|F_j^\prime \setminus F_{k}^\prime| = 1 \text{ and } F_i^\prime \cap F_{j}^\prime \subseteq F_{k}^\prime \subseteq F_i^\prime \cup F_{j}^\prime.
\]

This shows that $>^\prime$ is a strong shelling order of $\text{link}_\Delta(A)$. \qed

**Example 2.14.** Note that even when both $\text{link}_\Delta(x)$ and $\Delta \setminus x$ are pure strongly shellable, $\Delta$ may not necessarily be strongly shellable. For example, let $\Delta$ be the complex whose facet set is
\[
\{ \{1, 2, 3\}, \{2, 3, 4\}, \{3, 4, 5\}, \{4, 5, 6\}, \{5, 6, 7\} \}.
\]

One can check directly that $\text{link}_\Delta(7)$ and $\Delta \setminus 7$ are pure strongly shellable. On the other hand, notice that
\[
\text{dis}_\Delta(\{1, 2, 3\}, \{5, 6, 7\}) = 3,
\]
while
\[
\text{dis}_{\Delta(\Delta)}(\{1, 2, 3\}, \{5, 6, 7\}) = 4.
\]

Thus, again by Theorem 3.11, we see that $\Delta$ is not strongly shellable.

**Proposition 2.15.** Assume that $\Delta$ is a strongly shellable complex, and let $S$ be some subset of the set of vertices of $\Delta$. Assume furthermore that the induced complex $\Delta[S]$ satisfies the following condition:

if $\sigma$ is a maximal simplex in $\Delta$, then $\sigma \cap \Delta[S] = \sigma[S]$ is a maximal simplex in $\Delta[S]$.

In this case, the complex $\Delta[S]$ is strongly shellable as well, and any strong shelling order on $\mathcal{F}(\Delta)$ induces a strong shelling order on $\mathcal{F}(\Delta[S])$. 
Proof. Let > be a strong shelling order on $\mathcal{F}(\Delta)$. For each $F \in \mathcal{F}(\Delta[S])$, let $\tilde{F}$ be the first facet in $\mathcal{F}(\Delta)$ with respect to $>$ such that $\tilde{F} \cap S = F$. Then, we have the following induced order $>_S$ on $\mathcal{F}(\Delta[S])$:

$$\text{for each } F, G \in \mathcal{F}(\Delta[S]), \quad F >_S G \text{ if and only if } \tilde{F} > \tilde{G}.$$ 

To check that $>_S$ is a strong shelling order, we take arbitrary $F, G \in \mathcal{F}(\Delta[S])$ with $F >_S G$. Thus, $\tilde{F} > \tilde{G}$. As $>$ is a strong shelling order, one can find an $L' \in \mathcal{F}(\Delta)$ such that $L' > \tilde{G}$ and satisfies:

$$|\tilde{G} \setminus L'| = 1 \quad \text{and} \quad \tilde{F} \cap \tilde{G} \subseteq L' \subseteq \tilde{F} \cup \tilde{G}.$$

Assume that $L := L' \cap S$ and $\tilde{G} \setminus L' = \{a\}$.

We claim that $a \in G \setminus L$. In fact, it is easy to see that $a \not\in L$ since $a \not\in L'$. On the other hand, if $a \not\in G$, then $G \subseteq L' \cap S$, i.e., $G \subseteq L$. Note that $L$ and $G$ are facets of $\Delta[S]$, so $L = G$. However, we will have $L' \cap S = \tilde{G} \cap S$ and $L' > \tilde{G}$. This contradicts to the assumption that $\tilde{G}$ is the first facet in $\mathcal{F}(\Delta)$ whose restriction to $S$ is $G$.

Consequently, $a \in G \setminus L \subseteq \tilde{G} \setminus L' = \{a\}$, and hence $|G \setminus L| = 1$. On the other hand, it is clear that $F \cap G \subseteq L \subseteq F \cup G$. Finally, $\tilde{L} \geq L' > \tilde{G}$, hence $L >_S G$. Thus $>_S$ is a strong shelling order of $\Delta[S]$.

Recall that if $\Gamma$ and $\Delta$ are two complexes over disjoint vertex sets, the join of them is the complex on the vertex set $\mathcal{V}(\Gamma) \cup \mathcal{V}(\Delta)$:

$$\Gamma \ast \Delta := \{ F \cup G \mid F \in \Gamma \text{ and } G \in \Delta \}.$$ 

It is well-known that the join of two complexes is shellable if and only if each of the complexes is shellable; see [4, Remark 10.22]. We also have a strongly shellable version here.

**Proposition 2.16.** Let $\Gamma$ and $\Delta$ be two complexes. Then the join complex $\Gamma \ast \Delta$ is strongly shellable if and only if both $\Gamma$ and $\Delta$ are strongly shellable.

**Proof.** Assume that $\Gamma$ and $\Delta$ are strongly shellable. Let $>_1$ and $>_2$ be two strong shelling orders on $\mathcal{F}(\Gamma)$ and $\mathcal{F}(\Delta)$, respectively. Let $>$ be the lexicographic order with respect to $(>_1,>_2)$ on $\mathcal{F}(\Gamma \ast \Delta)$, namely, for $F_1, F_2 \in \mathcal{F}(\Gamma)$ and $G_1, G_2 \in \mathcal{F}(\Delta)$, $F_1 \cup G_1 > F_2 \cup G_2$ precisely whenever either $F_1 >_1 F_2$, or $F_1 = F_2$ and $G_1 >_2 G_2$.

To check the strong shellability of $>$, it suffices to take distinct $F_1, F_2 \in \mathcal{F}(\Gamma)$ and distinct $G_1, G_2 \in \mathcal{F}(\Delta)$ such that $F_1 \cup G_1 > F_2 \cup G_2$. Then $F_1 >_1 F_2$. We can choose $F_3$ such that $F_3 >_1 F_2$ in $\mathcal{F}(\Gamma)$, and satisfies:

$$|F_2 \setminus F_3| = 1 \quad \text{and} \quad F_1 \cap F_2 \subseteq F_3 \subseteq F_1 \cup F_2.$$

It is clear that $F_3 \cup G_2 > F_2 \cup G_2$, and satisfies

$$|(F_2 \cup G_2) \setminus (F_3 \cup G_2)| = 1$$

with

$$(F_1 \cup G_1) \cap (F_2 \cup G_2) \subseteq (F_3 \cup G_2) \subseteq (F_1 \cup G_1) \cup (F_2 \cup G_2).$$

Thus $>$ is a strong shelling order of $\Gamma \ast \Delta$.

For the other direction, we can apply Proposition 2.15 by using $S = \mathcal{V}(\Gamma)$ and $S = \mathcal{V}(\Delta)$, respectively.

Definition 2.17. Let $\Delta$ be a simplicial complex with the vertex set $V(\Delta) = \{x_1, \ldots, x_n\}$ and $s_1, \ldots, s_n$ be arbitrary positive integers. The $(s_1, \ldots, s_n)$-expansion of $\Delta$, denoted by $\Delta^{(s_1, \ldots, s_n)}$, is the simplicial complex with the vertex set $\{x_{i,j} \mid 1 \leq i \leq n, 1 \leq j \leq s_i\}$ and the facet set
\[
\{x_{i_1,r_1}, \ldots, x_{i_t,r_t} \mid x_{i_1}, \ldots, x_{i_t} \in F(\Delta) \text{ and } (r_1, \ldots, r_t) \in [s_{i_1}] \times \cdots \times [s_{i_t}]\}.
\]

Now, we wrap up this section with the following strongly shellable version of [13, Corollary 2.15].

Theorem 2.18. Assume that $s_1, \ldots, s_n$ are positive integers. Then $\Delta$ is strongly shellable if and only if $\Delta^{(s_1, \ldots, s_n)}$ is so.

Proof. For simplicity, we will write $\Delta'$ for $\Delta^{(s_1, \ldots, s_n)}$.

(a) The “only if” part: By induction, it suffices to consider the special case when $s_k = 1$ for $k = 2, \ldots, n$. Let $f : V(\Delta') \rightarrow V(\Delta)$ be the map by assigning each $x_{i,j}$ to $x_i$ and extend it to be a map from $\Delta'$ to $\Delta$. Let $\succ_\Delta$ be a strong shelling order on $F(\Delta)$. Consider two distinct facets $F_1, F_2 \in F(\Delta')$.

(i) If $f(F_1) \neq f(F_2)$, we define $F_1 \succ_\Delta^* F_2$ if and only if $f(F_1) \succ_\Delta f(F_2)$.

(ii) If $f(F_1) = f(F_2)$, then $F_1 = \{x_{i_1}, x_{i_2,1}, \ldots, x_{i_t,1}\}$ and $F_2 = \{x_{i_1}, x_{i_2,1}, \ldots, x_{i_t,1}\}$ for suitable $x_{i_1}, \ldots, x_{i_t} \in V(\Delta) \setminus \{x_1\}$. In this case, we define $F_1 \succ_\Delta^* F_2$ if and only if $i < j$.

Now, we show that $\succ_\Delta^*$ defines a strong shelling order on $F(\Delta')$. Indeed, we only need to check two distinct edges $F_1 \succ_\Delta^* F_2$ such that $f(F_1) \neq f(F_2)$. Whence, $f(F_1) \succ_\Delta f(F_2)$. Since $\Delta$ is strongly shellable, one can find $\tilde{F}_3 \in F(\Delta)$ such that $\tilde{F}_3 \succ_\Delta f(F_2)$.

We will construct a facet $F_3 \in F(\Delta')$ with $f(F_3) = \tilde{F}_3$ accordingly. Take arbitrary $x_i \in \tilde{F}_3$ and we will find the $x_{i,j}$ for $F_3$. Here, if $i \neq 1$, $j$ is forced to be 1. If $x_1 \in \tilde{F}_3$, then $x_1 \in f(F_1) \cup f(F_2)$. We have two sub-cases here. If $x_1 \in f(F_1)$, we will take the $j$ such that $x_{1,j} \in F_2$. Otherwise, we will take the $j$ such that $x_{1,j} \in F_1$.

In the following, we verify that $F_3$ is the expected facet proceeding $F_2$ with respect to $\succ_\Delta^*$.

(1) As $f(F_3) = \tilde{F}_3 \succ_\Delta^* f(F_2)$, $F_3 \succ_\Delta^* F_2$.

(2) Now, suppose that $\{x_k\} = f(F_2) \setminus \tilde{F}_3$. If $k \neq 1$, obviously $F_2 \setminus F_3 = \{x_k, 1\}$. If $k = 1$, then $F_2 \setminus F_3 = \{x_{i,j}\}$ for the unique $x_{i,j} \in F_2$. In both cases, $|F_2 \setminus F_3| = 1$.

(3) For $i \neq 1$, then $x_{i,1} \in F_3$ if and only if $x_i \in \tilde{F}_3$. On the other hand, $x_{i,1} \in f(F_1)$ or $f(F_2)$ if and only if $x_i \in F_1$ or $F_2$ respectively. Thus
\[
F_1 \cap F_2 \cap \{x_{i,1}\} \subseteq F_3 \cap \{x_{i,1}\} \subseteq (F_1 \cup F_2) \cap \{x_{i,1}\}.
\]

For $i = 1$, we may assume that $x_1 \in f(F_1) \cup f(F_2)$. Write $X_1 = \{x_{1,1}, \ldots, x_{1,s_1}\}$. Depending on whether $x_1 \in f(F_2)$ or not, we have $F_3 \cap X_1 = F_2 \cap X_1$ or $F_1 \cap X_1$. Thus,
\[
F_1 \cap F_2 \cap X_1 \subseteq F_3 \cap X_1 \subseteq (F_1 \cup F_2) \cap X_1.
\]

To sum up, we have $F_1 \cap F_2 \subseteq F_3 \subseteq F_1 \cup F_2$.

Therefore, $\succ_\Delta^*$ is a strong shelling order on $\Delta'$.

(b) The “if” part: Let $\succ_\Delta^*$ be a strong shelling order on $F(\Delta')$. We will identify $x_{i,1} \in V(\Delta')$ with $x_i \in V(\Delta)$, treating $\Delta$ as a subcomplex of $\Delta'$. Thus, one has a natural induced linear order $\succ_\Delta$ on $F(\Delta)$. It suffices to show that $\succ_\Delta$ is a strong shelling order.
Take two distinct facets $F_1 \triangleright_{\Delta} F_2$ in $\mathcal{F}(\Delta) \subset \mathcal{F}(\Delta')$. Thus, by the strong shellability of $\Delta'$, one has $F_1 \in \mathcal{F}(\Delta')$ with $F_3 \triangleright_{\Delta} F_2$, $|F_2 \setminus F_3| = 1$ and $F_1 \cap F_2 \subseteq F_3 \subseteq F_1 \cup F_2$. As $F_1 \cup F_2 \subset \mathcal{V}(\Delta)$, $F_3 \subset \mathcal{V}(\Delta)$. In particular, $F_3 \in \mathcal{F}(\Delta)$. Therefore, $F_3 \triangleright_{\Delta} F_2$. □

3. Codimension one graph

Zheng [17] considered the following property of simplicial complexes.

**Definition 3.1.** A complex is called *connected in codimension one* if for any two facets $F$ and $G$ with $\dim(F) \geq \dim(G)$, there exists a chain of facets $F = F_0, \ldots, F_n = G$ between $F$ and $G$ such that $\dim(F_i \cap F_{i+1}) = \dim(F_{i+1}) - 1$ for all $i = 0, \ldots, n-1$.

**Lemma 3.2** ([6, Lemma 9.1.12]). *Every Cohen-Macaulay complex is connected in codimension one.*

As pure shellable complexes are Cohen-Macaulay by [6, Theorem 8.2.6], the following simple result follows easily from the definition.

**Corollary 3.3.** Let $\Delta$ be a pure shellable complex. Then there exists a linear order on $\mathcal{F}(\Delta)$, say $F_1, \ldots, F_m$, such that $\langle F_1, \ldots, F_k \rangle$ is connected in codimension one for each $k \in [m]$.

**Definition 3.4.** For a complex $\Delta$, the *distance* between two facets $F_1$ and $F_2$ is defined by

$$\text{dis}(F_1, F_2) := \min(\dim(F_1), \dim(F_2)) - \min(\dim(F_1 \cap F_2), \dim(F_1 \setminus F_2), \dim(F_2 \setminus F_1)),$$

which can be easily verified to be $\min(|F_1 \setminus F_2|, |F_2 \setminus F_1|)$. Sometimes, we will also write it as $\text{dis}_{\Delta}(F_1, F_2)$, in order to emphasize the underlying complex.

Note that in the pure case, the function $\text{dis}_{\Delta}$ satisfies the usual triangle inequality. However, this is generally false in the nonpure case.

**Lemma 3.5.** Let $\Delta$ be a complex. If $F, G, H$ are three facets such that

$$\min(\dim(F), \dim(G)) \leq \dim(H) \leq \max(\dim(F), \dim(G)),$$

then $\text{dis}(F, H) + \text{dis}(H, G) = \text{dis}(F, G)$ if and only if $F \cap G \subseteq H \subseteq F \cup G$.

**Proof.** As indicated in Figure 2, we may assume that $F = P_1 \cup P_2 \cup P_4 \cup P_5$, $G = P_1 \cup P_5 \cup P_4 \cup P_7$ and $H = P_1 \cup P_2 \cup P_3 \cup P_6$. Suppose that $\dim(F) \geq \dim(G)$. Therefore, indeed, $\dim(F) \geq \dim(H) \geq \dim(G)$. In this case, $\text{dis}(F, H) = |H \setminus G| = |P_3| + |P_6|$, $\text{dis}(H, G) = |G \setminus H| = |P_4| + |P_7|$ and $\text{dis}(F, G) = |G \setminus F| = |P_3| + |P_7|$. Thus, the condition $\text{dis}(F, H) + \text{dis}(H, G) = \text{dis}(F, G)$ is translated into $|P_3| + |P_6| = 0$, i.e., $P_4 = P_6 = \emptyset$. But this is equivalent to saying that $F \cap G \subseteq H \subseteq F \cup G$. □

![Venn diagram of 3 intersecting sets](image-url)
Corollary 3.6. Under the assumptions in Proposition 2.15, let $F_1, F_2$ be two distinct facets of $\Delta$ such that $F_1 \cap S = F_2 \cap S$. If $G$ is another facet such that
\[
\min(\dim(F_1), \dim(F_2)) \leq \dim(G) \leq \max(\dim(F_1), \dim(F_2))
\]
and
\[
\text{dis}(F_1, G) + \text{dis}(G, F_2) = \text{dis}(F_1, F_2),
\]
then $G \cap S = F_1 \cap S$.

Proof. Without loss of generality, we assume that $\dim(F_1) \geq \dim(G) \geq \dim(F_2)$. By Lemma 3.5, we have $F_1 \cap F_2 \subseteq G \subseteq F_1 \cup F_2$, and thus $(F_1 \cap S) \cap (F_2 \cap S) \subseteq G \cap S \subseteq (F_1 \cap S) \cup (F_2 \cap S)$. As $F_1 \cap S = F_2 \cap S$, we have $G \cap S = F_1 \cap S$. \qed

In the above corollary, the condition on dimensions is necessary, as the following example shows.

Example 3.7. Let $\Delta$ be a complex on the set $\{1, 2, 3, 4, 5, 6, 7\}$ whose facet set is
\[
\{ F_1 = \{1, 2, 3, 4\}, \ F_2 = \{4, 5, 6\}, \ G = \{1, 2, 3, 5, 6, 7\} \}.
\]
It is direct to check that $\text{dis}(F_1, G) + \text{dis}(G, F_2) = \text{dis}(F_1, F_2)$. If $S = \{4, 7\}$, then $F_1 \cap S = F_2 \cap S = \{4\}$, but $G \cap S = \{7\} \neq F_1 \cap S$.

Note that every finite graph $\Gamma$ has a well-defined distance function defined from $V(\Gamma)^2$ to $\mathbb{N} \cup \{+\infty\}$. We will denote it by $\text{dis}_\Gamma$.

Definition 3.8. Given a complex $\Delta$, the codimension one graph related to $\Delta$, denoted by $\Gamma(\Delta)$, is a finite simple graph whose vertex set is $F(\Delta)$, and two facets $F$ and $G$ are adjacent in $\Gamma(\Delta)$ if and only if $\text{dis}_\Delta(F, G) = 1$. The codimension one graph $\Gamma(\Delta)$ will be called harmonious with respect to $\Delta$ if $\text{dis}_\Delta(F, G) = \text{dis}_{\Gamma(\Delta)}(F, G)$ for every pair of facets $F$ and $G$. In this case, we also call $\Delta$ a harmonious complex.

Example 3.9. Let $\Delta$ be the complex whose facets are $\{1, 2\}$, $\{2, 3\}$, $\{3, 4\}$ and $\{4, 5\}$. The codimension one graph of $\Delta$ is pictured in Figure 3. For simplicity, in this figure, we write $x_{i,j}$ for the vertex corresponding to the facet $\{i, j\}$. Note that

\[
\text{dis}_{\Gamma(\Delta)}(\{1, 2\}, \{4, 5\}) = 3 \neq \text{dis}_\Delta(\{1, 2\}, \{4, 5\}) = 2.
\]

Hence $\Delta$ is not a harmonious complex.

Lemma 3.10. If $\Delta$ is a Cohen-Macaulay complex, then $\Gamma(\Delta)$ is connected.

Proof. This is simply a paraphrase of Lemma 3.2. \qed

We will have more control regarding the connectivity when strong shellability is present.

Lemma 3.11. Let $\Delta$ be a strongly shellable complex. Then $\text{dis}_{\Gamma(\Delta)}(F, G) \leq \text{dis}_\Delta(F, G)$ for each pair of facets $F, G \in \Delta$. In particular, $\Gamma(\Delta)$ is connected.
Proof. Let $F_1, F_2, \cdots, F_t$ be a dimension-decreasing strong shelling order. We will prove by induction on the distance $\mathrm{dis}_\Delta(F,G)$. The case $\mathrm{dis}_\Delta(F,G) = 0$ is trivial. Thus, we will assume that $F \neq G$ and $\mathrm{dis}_\Delta(F,G) > 0$. Let $F = F_i$ and $G = F_j$ with $i < j$. Then there exists $k < j$, such that $|F_j \setminus F_i| = 1$ and $F_i \cap F_k \subseteq F_k \subseteq F_i \cup F_j$. Obviously, $\mathrm{dis}_\Delta(F_k, F_j) = 1 = \mathrm{dis}_\Delta(F_k, F_j)$. We have the following two subcases:

1. $\dim(F_k) \leq \dim(F_i)$. In this case, $\mathrm{dis}_\Delta(F_i, F_k) = |F_k \setminus F_i|$ and $\mathrm{dis}_\Delta(F_i, F_j) = |F_j \setminus F_i|$. Since $|F_j \setminus F_i| = |F_k \setminus F_i| + 1$ by Remark 2.3, it follows that $\mathrm{dis}_\Delta(F_i, F_k) = \mathrm{dis}_\Delta(F_i, F_j) - 1$.

2. $\dim(F_k) > \dim(F_i)$. In this case, $\mathrm{dis}_\Delta(F_k, F_j) = |F_j \setminus F_k|$. Since $\mathrm{dis}_\Delta(F_i, F_j) = |F_j \setminus F_i| + 1$, it follows that $\mathrm{dis}_\Delta(F_k, F_j) < \mathrm{dis}_\Delta(F_i, F_j) - 1$.

By inductive assumption, $\mathrm{dis}_\Delta(F_i, F_k) \leq \mathrm{dis}_\Delta(F_i, F_j)$. Hence

$$\mathrm{dis}_\Delta(F_i, F_j) \leq \mathrm{dis}_\Delta(F_i, F_k) + 1 \leq \mathrm{dis}_\Delta(F_i, F_k) + 1 \leq \mathrm{dis}_\Delta(F_i, F_j).$$

The above proof indicates that the appearance of $F_k$ in the case (2) induces the strict inequality $\mathrm{dis}_\Delta(F_i, F_j) < \mathrm{dis}_\Delta(F_i, F_j)$. Thus, we have the following result.

**Lemma 3.12.** Let $\Delta$ be a strongly shellable complex, and $\succ$ be a dimension-decreasing strong shelling order on $\mathcal{F}(\Delta)$. If $\Gamma(\Delta)$ is harmonious with respect to $\Delta$, then for each pair $F_i > F_j$, there exists a facet $F_k > F_j$, such that:

1. $|F_j \setminus F_i| = 1$ and $F_i \cap F_j \subseteq F_k \subseteq F_i \cup F_j$;

2. $\dim(F_i) \leq \dim(F_k) \leq \dim(F_j)$.

In particular, $\mathrm{dis}(F_i, F_j) = \mathrm{dis}(F_i, F_k) + \mathrm{dis}(F_k, F_j)$ with $\mathrm{dis}(F_k, F_j) = 1$.

**Remark 3.13.** As a matter of fact, if $\Delta$ is harmonious, then it is clear from the proof of Lemma 3.11 that any $F_k$ satisfying the condition (1) in Lemma 3.12 will automatically satisfy the condition (2) as well.

**Definition 3.14.** A complex $\Delta$ will be called *quasi-harmonious*, if there exists a dimension-decreasing strong shelling order $\succ$ on $\mathcal{F}(\Delta)$, such that for each pair $F_i > F_j$, there exists a facet $F_k > F_j$ such that $F_k$ satisfies the conditions (1) and (2) in Lemma 3.12.

Obviously, strongly shellable harmonious complexes are quasi-harmonious. Later, in Theorem 4.7, we will show that pure strongly shellable complexes are harmonious. Hence pure strongly shellable complexes are always quasi-harmonious. But in the nonpure case, a strongly shellable complex may not necessarily be quasi-harmonious.

**Example 3.15** (Strongly shellable, but not quasi-harmonious). Let $\Delta$ be a complex with facets

$$\{3, 4, 5, 6, 7\}, \{2, 4, 5, 6, 7\}, \{2, 3, 5, 6, 7\}, \{2, 3, 4, 6, 7\}, \{2, 3, 4, 5\}, \{1, 6, 7\}.$$ 

One can check directly that $\Delta$ is a nonpure strongly shellable complex. But for the facets $\{2, 3, 4\}$ and $\{1, 6, 7\}$, the condition for being quasi-harmonious is not satisfied.

On the other hand, nonpure quasi-harmonious complexes are generally not harmonious.

**Example 3.16** (Quasi-harmonious, but not harmonious). Let $\Delta$ be a complex with facets

$$\{2, 3, 5, 6\}, \{1, 2, 3\}, \{2, 3, 4\}, \{3, 4, 5\}, \{4, 5, 6\}.$$ 

One can check directly that this strongly shellable complex is a quasi-harmonious, but not harmonious.
However, the distance function does behave more tamely for quasi-harmonious complexes.

**Proposition 3.17.** Suppose that the simplicial complex $\Delta$ is quasi-harmonious with respect to the dimension-decreasing strong shelling order $\succ$ on $\mathcal{F}(\Delta)$. Then, for each pair of facets $F_i > F_j$, there exists a sequence of facets $F_i = G_0, G_1, \ldots, G_t = F_j$ such that

(a) $t = \text{dis}(F_i, F_j)$;
(b) $\dim(G_0) \geq \dim(G_1) \geq \cdots \geq \dim(G_t)$;
(c) $\text{dis}(G_h, G_{h+1}) = 1$ for each $h$ with $0 \leq h \leq t - 1$.

**Proof.** Assume that $t = \text{dis}(F_i, F_j)$ and $F_k$ is the facet as in Lemma 3.12. It suffices to consider the case when $t \geq 2$. Whence, $F_i \neq F_k$. Denote $F_i, F_k$ and $F_j$ by $G_0, G_{t-1}$ and $G_t$ respectively.

1. If $F_i > F_k$, by induction, we will have a sequence of facets $G_0, G_1, \ldots, G_{t-1}$ such that $\dim(G_0) \geq \dim(G_1) \geq \cdots \geq \dim(G_{t-1})$, and $\text{dis}(G_h, G_{h+1}) = 1$ for each $h$ with $0 \leq h \leq t - 2$.
2. If $F_k > F_i$, then $\dim(F_i) = \dim(F_k)$. Again by induction, we will have a sequence of facets $G_0, G_1, \ldots, G_{t-1}$ of same dimension with $\text{dis}(G_h, G_{h+1}) = 1$ for each $h$ with $0 \leq h \leq t - 2$.

In either case, we are done after concatenating the sequence with $G_t$ in the end. \hfill $\square$

The harmonious property behaves well with respect to restrictions of strong shellability.

**Lemma 3.18.** Let $\Delta$ be a harmonious strongly shellable complex. Let $S$ be a non-empty subset of $\mathcal{F}(\Delta)$ and $\Delta' = \langle S \rangle$. If $\Delta'$ is also strongly shellable, then it is harmonious as well.

**Proof.** Take arbitrary $F_a, F_b \in \mathcal{F}(\Delta')$. As any minimal path connecting $F_a$ and $F_b$ in $\Gamma(\Delta')$ is a path connecting $F_a$ and $F_b$ in $\Gamma(\Delta)$, one has $\text{dis}\Gamma(\Delta')(F_a, F_b) \geq \text{dis}\Gamma(\Delta)(F_a, F_b) = \text{dis}(F_a, F_b)$. But $\text{dis}\Gamma(\Delta')(F_a, F_b) \leq \text{dis}(F_a, F_b)$ by Lemma 3.11. Consequently, $\text{dis}\Gamma(\Delta')(F_a, F_b) = \text{dis}(F_a, F_b)$. \hfill $\square$

For a given linear order $\succ$ on $\mathcal{F}(\Delta)$, a facet $F$ of dimension $k$ is called an initial facet, if $F \succ G$ for any other facet $G$ of same dimension. One can similarly define terminal facet. Meanwhile, for any facet $F_1, F_2$, we have the interval $[F_1, F_2]_\succ := \{ G \in \mathcal{F}(\Delta) \mid F_1 \succ G \succ F_2 \}$.

**Proposition 3.19.** Let $\Delta$ be a harmonious strongly shellable complex with a dimension-decreasing strong shelling order $\succ$ on $\mathcal{F}(\Delta)$. If $F_i$ is an initial facet of $\succ$, then for every $F_j$ with $F_i \succ F_j$, the interval $[F_i, F_j]_\succ$ generates a harmonious strongly shellable complex.

**Proof.** By Lemma 3.12, for each pair of facets $F_a, F_b \in [F_i, F_j]_\succ$ with $F_a > F_b$, there exists a facet $F_c > F_b \succ F_j$, such that $|F_i \setminus F_c| = 1$, $F_a \cap F_b \subseteq F_c \subseteq F_a \cup F_b$, and $\dim(F_c) \leq \dim(F_a)$. Since $F_i$ is an initial facet, and $\succ$ is dimension-decreasing, $\dim F_a \leq \dim F_i$. Thus, $F_c \in [F_i, F_j]_\succ$. This shows that $[F_i, F_j]_\succ$ generates a strongly shellable complex. As for the expected harmonious property, we apply Lemma 3.18. \hfill $\square$

**Corollary 3.20.** Let $\Delta$ be a harmonious strongly shellable complex. Then $\mathcal{F}(\Delta)$ is also harmonious strongly shellable for any $0 < k \leq \dim(\Delta)$.

**Proof.** Take arbitrary dimension-decreasing strong shelling order $\succ$ on $\mathcal{F}(\Delta)$. Let $F_i$ and $F_j$ be the initial and terminal facet of dimension $k$ respectively. Then $\mathcal{F}(\Delta) = [F_i, F_j]_\succ$. Now, we apply Proposition 3.19. \hfill $\square$
4. Strongly shellable complexes, pure case

In this section, we focus on pure strongly shellable complexes. In this case, the distance function \( \text{dis}_\Delta \) in Definition 3.4 satisfies the usual triangle inequality:

\[
\text{dis}(F, H) + \text{dis}(H, G) \geq \text{dis}(F, G) \quad \text{for } F, H, G \in F(\Delta).
\]

The following lemma is the pure version of Lemma 3.5.

**Lemma 4.1.** Let \( F, G, H \in \binom{[n]}{d} \). Then \( \text{dis}(F, H) + \text{dis}(H, G) = \text{dis}(F, G) \) if and only if \( F \cap G \subseteq H \subseteq F \cup G \).

The following fact follows directly from the definition and the above lemma:

**Lemma 4.2.** Let \( \Delta \) be a pure complex. Then \( \Delta \) is strongly shellable if and only if there exists a linear order \( > \) on \( F(\Delta) \), such that whenever \( F_i > F_j \), there exists a facet \( F_k > F_j \), such that \( \text{dis}(F_k, F_j) = 1 \) and \( \text{dis}(F_i, F_k) = \text{dis}(F_i, F_j) - 1 \).

Given a linear order \( > \) on \( F(\Delta) \), if \( F \succ G \), we will say that \( F \) is on the left side of \( G \).

Similar to the phenomenon in Proposition 3.17, pure strongly shellable complexes can be further characterized by the distance function as follows.

**Proposition 4.3.** The following statements are equivalent for a pure simplicial complex \( \Delta \):

(a) \( \Delta \) is strongly shellable.

(b) There exists a linear order \( > \) on \( F(\Delta) \), such that for each pair \( F, G \in F(\Delta) \) with \( F > G \), there exists a chain of facets \( F = H_0, \ldots, H_t = G \) of length \( t = \text{dis}(F, G) \) on the left side of \( G \) with \( \text{dis}(H_{l-1}, H_l) = 1 \) for \( 0 \leq l \leq t \).

(c) There exists a linear order \( > \) on \( F(\Delta) \), such that for each pair \( F, G \in F(\Delta) \) with \( F > G \), there exists a chain of facets \( F = H_0, \ldots, H_t = G \) of length \( t = \text{dis}(F, G) \) on the left side of \( G \) with \( \text{dis}(H_{l-1}, H_l) = l_2 - l_1 \) for \( 0 \leq l_1 \leq l_2 \leq t \).

(d) There exists a linear order \( > \) on \( F(\Delta) \), such that for each pair \( F, G \in F(\Delta) \) with \( F > G \), either \( \text{dis}(F, G) = 1 \), or \( \text{dis}(F, G) \geq 2 \) and there exists some \( H > G \) with \( F \neq H \) such that \( \text{dis}(F, H) + \text{dis}(H, G) = \text{dis}(F, G) \).

(e) There exists a linear order \( > \) on \( F(\Delta) \), such that for each pair \( F, G \in F(\Delta) \) with \( F > G \), either \( \text{dis}(F, G) = 1 \), or \( \text{dis}(F, G) \geq 2 \) and there exists some \( H > G \) with \( F \neq H \) such that \( F \cap G \subseteq H \subseteq F \cup G \).

**Proof.** The implications (d) \( \iff \) (e) follows from Lemma 4.1. The implications (d) \( \iff \) (a) \( \iff \) (b) \( \iff \) (c) are clear from Lemma 4.2.

(i) The implication (a) \( \iff \) (c) is straightforward as follows. Assume that \( F > G \). If \( t = \text{dis}(F, G) = 1 \), this is clear. Thus, we may assume that \( t \geq 2 \). Write \( F = H_0 \) and \( G = H_t \). Therefore, there exists \( H_{t-1} > H_t \) with \( \text{dis}(H_{t-1}, H_t) = 1 \) and \( \text{dis}(H_0, H_{t-1}) = t - 1 \).

If \( H_0 > H_{t-1} \), by induction, we can find \( H_0, H_1, \ldots, H_{t-1} \) on the left side of \( H_{t-1} \) such that \( \text{dis}(H_{l-1}, H_l) = l_2 - l_1 \) for \( 0 \leq l_1 \leq l_2 \leq t - 1 \). Now take \( 0 \leq l \leq t - 1 \) and check \( \text{dis}(H_t, H_l) \). Obviously, \( \text{dis}(H_l, H_t) \leq \text{dis}(H_t, H_{t-1}) + \text{dis}(H_{t-1}, H_l) = (t - 1 - l) + 1 = t - l \).

On the other hand, \( \text{dis}(H_l, H_t) \geq \text{dis}(H_0, H_t) - \text{dis}(H_0, H_l) = t - l \). Thus, \( \text{dis}(H_l, H_t) = t - l \), as expected.

The case when \( H_{t-1} > H_0 \) is similar. By induction, we will find a chain of facets \( H_{t-1} = H_0', H_1', \ldots, H_{t-1}' = H_0 \) on the left of \( H_0 \) with \( \text{dis}(H_0', H_2') = l_2 - l_1 \) for \( 0 \leq l_1 \leq l_2 \leq t - 1 \).
As a final step, we show the following is the first main result of this section.

(ii) As a final step, we show (d) ⇒ (a), which is also easy. Take arbitrary $F > G$. We show that there exists some $L$ with $L \succneq G$, $\text{dis}(L,G) = 1$ and $\text{dis}(F,L) = \text{dis}(F,G) - 1$. To show this, we may assume that $t = \text{dis}(F,G) \geq 2$. Therefore, there exists some $H \succneq G$ with $F \neq H$ and $\text{dis}(F,H) + \text{dis}(H,G) = t$. As $1 \leq \text{dis}(H,G) \leq t - 1$, by induction, we can find $L > G$ such that $\text{dis}(L,G) = 1$ and $\text{dis}(H,L) = \text{dis}(H,G) - 1$. Now, $\text{dis}(F,L) \leq \text{dis}(F,H) + \text{dis}(H,L) = (t - \text{dis}(H,G)) + (\text{dis}(H,G) - 1) = t - 1$. On the other hand, $\text{dis}(F,L) \geq \text{dis}(F,G) - \text{dis}(L,G) = t - 1$. Therefore, $\text{dis}(F,L) = t - 1$, as expected. 

In the following, we will characterize the strong shellability of a pure complex by investigating its codimension one graph.

**Definition 4.4.** For a given finite simple graph $G$, we can delete a vertex $v_1$ to get a subgraph $G_1 = G \setminus v_1$. If for each pair of vertices $u, v$ in $G_1$, $\text{dis}_{G_1}(u,v) = \text{dis}_{G}(u,v)$, the graph $G_1$ is called distance-preserving with respect to $G$. More generally, if we can order the vertex set $V(G) = \{v_1, v_2, \ldots, v_t\}$, such that the induced subgraphs $G_k = G[\{v_{k+1}, v_{k+2}, \ldots, v_t\}]$ satisfy the requirement that $G_i$ preserves distance with respect to $G_{i-1}$ for each $1 \leq i < t - 1$, then we say that the graph $G$ has a distance-preserving order: $v_1, v_2, \ldots, v_t$.

**Example 4.5.** Let $\Delta$ be a pure complex with the facet set

\[
\{\{1, 2, 3, 4\}, \{2, 3, 4, 5\}, \{3, 4, 5, 6\}, \{4, 5, 6, 7\}, \{1, 4, 6, 7\}, \{1, 2, 4, 7\}\}.
\]

The codimension one graph $\Gamma(\Delta)$ is a cycle with 6 vertices, as Figure 4 shows. It is easy to check that $\Gamma(\Delta)$ is harmonious but does not have any distance-preserving order.

![Figure 4. $\Gamma(\Delta)$](image)

As $\text{dis}_\Delta$ is indeed a distance metric on $\mathcal{F}(\Delta)$ in pure case, we have the following lemma.

**Lemma 4.6.** Let $\Delta$ be a pure complex. Then $\text{dis}_\Delta(F,G) \leq \text{dis}_{\Gamma(\Delta)}(F,G)$ for each pair of facets $F,G \in \Delta$.

**Proof.** Assume that $\text{dis}_{\Gamma(\Delta)}(F,G) = t$. If $F = F_0, F_1, \ldots, F_t = G$ is a path of length $t$ in $\Gamma(\Delta)$, then, for each $1 \leq i \leq t$, $|F_{i-1} \cap F_i| = d - 1$, i.e., $\text{dis}_{\Gamma}(F_{i-1}, F_i) = 1$. By the triangle inequality, $\text{dis}_\Delta(F,G) \leq t$.

The following is the first main result of this section.
**Theorem 4.7.** A pure complex $\Delta$ is strongly shellable if and only if its codimension one graph $\Gamma(\Delta)$ is harmonious and has a distance-preserving order.

**Proof.** For the necessity part: If $\Delta$ is strongly shellable, then for each pair of facets $F, G \in \Delta$, $\text{dis}_{\Gamma(\Delta)}(F, G) \leq \text{dis}_\Delta(F, G)$ by Lemma 3.11. On the other hand, by Lemma 4.6, $\text{dis}_\Delta(F, G) \leq \text{dis}_{\Gamma(\Delta)}(F, G)$. Hence $\Gamma(\Delta)$ is harmonious.

Since $\Delta$ is strongly shellable, we can assume that $G_1, G_2, \ldots, G_s$ is a strongly shelling order on $\mathcal{F}(\Delta)$. Note that each subcomplex $\langle G_1, \ldots, G_k \rangle$ for $1 \leq k \leq s$ is also strongly shellable, therefore harmonious, by the previous argument. It is clear that $G_s, G_{s-1}, \ldots, G_1$ gives a distance-preserving order on $\Gamma(\Delta)$.

For the sufficiency part: Assume that $\Gamma(\Delta)$ has a distance-preserving order: $G_n, G_{n-1}, \ldots, G_1$. Since $\Gamma(\Delta)$ is harmonious, the subcomplexes $\Delta_k := \langle G_1, \ldots, G_k \rangle$ are also harmonious for $1 \leq k \leq s$. In the following, we will show that $G_1, \ldots, G_s$ is a strong shelling order on $\mathcal{F}(\Delta)$. Take arbitrary facets $G_i, G_j \in \Delta$ with $i < j$ and suppose that $\text{dis}_\Delta(G_i, G_j) = t$. Let $\Gamma_j = \Gamma(\Delta_j)$. Since $\Delta_j$ is harmonious, $\text{dis}_{\Gamma_j}(G_i, G_j) = \text{dis}_\Delta(G_i, G_j) = t$. Therefore, there exists a path of length $t$ in $\Gamma_j$: $G_i = G_{k_1} \cup G_{k_2} \cup \cdots \cup G_{k_t} = G_j$, where $k_i \leq j$. Obviously, $\text{dis}_\Delta(G_{k_1}, G_j) = \text{dis}_{\Gamma_j}(G_{k_1}, G_j) = 1$. Note that $\text{dis}_\Delta(G_{k_1}, G_i) \geq \text{dis}_\Delta(G_{k_1}, G_j) - \text{dis}_\Delta(G_j, G_{k_1}) = t - 1$. On the other hand, $\text{dis}_{\Gamma_j}(G_{k_1}, G_i) \leq t - 1$ by the existence of the previous path connecting $G_i$ and $G_j$. Hence, by Lemma 4.6, we have $\text{dis}_\Delta(G_{k_1}, G_i) = \text{dis}_{\Gamma_j}(G_{k_1}, G_i) = t - 1$. It follows from Lemma 4.2 that $G_1, \ldots, G_s$ is a strong shelling order of $\Delta$.

Recall that a cycle in a finite simple graph $G$ is called minimal if there is no chord in the cycle. And the girth of $G$, denoted by $g(G)$, is the length of a shortest cycle contained in the graph. If a graph has no cycle, then its girth is assumed to be 0.

**Lemma 4.8.** Let $G$ be a connected simple graph. If it has a distance-preserving order, then its girth is at most 4.

**Proof.** We may assume that $G$ has at least one cycle, and has a distance-preserving order: $v_1, v_2, \ldots, v_{n+1}$. Let $G_k$ be the induced subgraph from $G$ by removing the vertices $v_1, \ldots, v_k$.

Assume for contradiction that $g(G) \geq 5$. As $G_{n-1}$ has no cycle, we can find the least $k$ such that $G_k$ has no cycle. Obviously $1 \leq k \leq n - 1$. From $G_{k-1}$ to $G_k$, we removed the vertex $v_k$. Thus, $v_k$ is contained in some minimal cycle in $G_{k-1}$. Consider one such minimal cycle. Let $v'$ and $v''$ be the two vertices adjacent to $v_k$ on this cycle. As $g(G) \geq 5$, and $G_{k-1}$ contains cycles, $g(G_{k-1}) \geq 5$. Thus, $v'$ and $v''$ are not adjacent in $G_{k-1}$ and indeed $\text{dis}_{G_{k-1}}(v', v'') = 2$. By the distance-preserving condition, $\text{dis}_{G_k}(v', v'') = 2$. This implies the existence of some vertex $u \in G_k$ which are adjacent to both $v'$ and $v''$. But $u \neq v_k$. Thus we have a cycle in $G_{k-1}$ consisting of the vertices $v_k, v', u$ and $v''$. This implies that $g(G_{k-1}) \leq 4$, a contradiction.

By Theorem 4.7 and Lemma 4.8, we have the following result.

**Proposition 4.9.** If $\Delta$ is a pure strongly shellable complex, then its codimension one graph $\Gamma(\Delta)$ is connected, and $g(\Gamma(\Delta)) \leq 4$, $\dim(\Gamma(\Delta)) \leq \dim(\Delta) + 1$.

We will wrap up this section with a very important property of pure strongly shellable complexes. We have already mentioned that any pure strongly shellable complex $\Delta$ (say, over the vertex set $[n]$) is Cohen-Macaulay, i.e., the Stanley-Reisner ring $\mathbb{K}[\Delta] = \mathbb{K}[x_1, \ldots, x_n]/I_\Delta$ is a Cohen-Macaulay ring over arbitrary field $\mathbb{K}$. This is an important property related to the Stanley-Reisner ideal $I_\Delta$ of $\Delta$. In the following, we will consider the facet ideal $I(\Delta) := \langle x^F | F \in \mathcal{F}(\Delta) \rangle \subseteq
Here, for any $F \subseteq [n]$, we write $x^F := \prod_{i \in F} x_i$. Notice that for any given simplicial complex $\Delta$, its complement complex $\Delta^c$ has the facet set $\mathcal{F}(\Delta^c) = \{ F^c : F \in \mathcal{F}(\Delta) \}$, where $F^c := V(\Delta) \setminus F$. The following observation is important.

**Lemma 4.10.** A pure complex $\Delta$ is strongly shellable if and only if its complement complex $\Delta^c$ has the same property.

**Proof.** Note that $\Delta^c$ is also a pure complex with $(\Delta^c)^c = \Delta$. Furthermore, for each pair of facets $A, B$ of $\Delta$, $\text{dis}_{\Delta^c}(A^c, B^c) = \text{dis}_{\Delta}(A, B)$. Thus, the result follows directly from Lemma 4.2. \(\square\)

Let $S = \mathbb{K}[x_1, \ldots, x_n]$ be a polynomial ring over a field $\mathbb{K}$ and $I$ a graded proper ideal. Recall that $I$ has linear quotients, if there exists a system of homogeneous generators $f_1, f_2, \ldots, f_m$ of $I$ such that the colon ideal $I_{f_i} = \{ f : f \in I, f \notin f_i \}$ is generated by linear forms for all $i$. If $I$ has linear quotients, then $I$ is componentwise linear; see [6, Theorem 8.2.15]. In particular, if $I$ has linear quotients and can be generated by forms of degree $d$, then it has a $d$-linear resolution; see [6, Proposition 8.2.1].

On the other hand, recall that the Alexander dual of $\Delta$ (with respect to the vertex set $V(\Delta)$), denoted by $\Delta^\vee$, is the complex $\Delta^\vee := \{ F^c : F \notin \Delta, F \subseteq [n] \}$. Note that $I_{\Delta^\vee} = I(\Delta^c)$ by [6, Lemma 1.5.3]. Thus, we have the second main result of this section.

**Theorem 4.11.** If $\Delta$ is a pure strongly shellable complex, then the facet ideal $I(\Delta)$ has linear quotients.

**Proof.** It is well-known that $\Delta$ is shellable if and only if $I_{\Delta^\vee}$ has linear quotients; see [6, Proposition 8.2.5]. Since $\Delta$ is strongly shellable, $\Delta^c$ is shellable by Lemma 4.10. Hence $I_{(\Delta^c)^\vee}$ has linear quotients. Note that $I_{(\Delta^c)^\vee} = I(\Delta)$. This completes the proof. \(\square\)

This important property will be vital for the sequel paper [5], where we deal with chordal (hyper)-graphs.

5. Strongly shellable posets

Recall that a poset $P$ is called bounded if it has a top element $\hat{1}$ and a bottom element $\hat{0}$. If $P$ is bounded, let $\mathcal{P} = P \cup \{ \hat{0}, \hat{1} \}$. Conversely, for any poset $P$, let $\hat{P} = P \cup \{ \hat{0}, \hat{1} \}$ where $\hat{0}$ and $\hat{1}$ are new elements adjoined so that $\hat{0} < x < \hat{1}$ for all $x \in P$. A finite poset is said to be pure if all maximal chains have the same length. And a poset is called graded if it is finite, bounded and pure.

Given a finite poset $P$, its order complex $\Delta(P)$ is the simplicial complex whose $k$-dimensional faces are the chains $x_0 < x_1 < \cdots < x_k$ of $P$. A finite pure poset $P$ will be called (strongly) shellable if its order complex $\Delta(P)$ is so. Note that a finite poset $P$ is (strongly) shellable if and only if $\hat{P}$ is so.

Let $P$ be a finite pure poset of length $r - 1$. Then $\hat{P}$ is graded with a well-defined rank function $\rho$, where $\rho(x)$ is defined to be the common length of all unrefinable chains from $\hat{0}$ to $x$ in $\hat{P}$. Obviously, $\rho(x) \in [r]$ for all $x \in P$. For any subset $S \subseteq [r]$, we define the rank-selected subposet $P_S$ by $\{ x \in P : \rho(x) \in S \}$. Like [2, Theorem 4.1], we have

**Proposition 5.1.** If $P$ is a purely strongly shellable poset of length $r - 1$, then $P_S$ is strongly shellable for all $S \subseteq [r]$.

**Proof.** The order complex $\Delta(P_S) = \Delta(P)[P_S]$. Obviously, if $\sigma$ is a maximal simplex in $\Delta(P)$, then $\sigma[P_S]$ is a maximal simplex in $\Delta(P_S)$. Now, we may apply Proposition 2.15. \(\square\)
The proof for [2, Proposition 4.2] also works for the following result:

**Proposition 5.2.** If \( P \) is a pure strongly shellable poset, then all intervals of \( P \) are strongly shellable.

**Proof.** The proof is standard. Assume that \( P \) is strongly shellable and that \([x, y]\) is an interval of \( P \). Let \( c : x_1 < x_2 < \cdots < x_g = x \) and \( d : y_1 < y_2 < \cdots < y_h \) be two unrefinable chains in \( P \) such that \( x_1 \) is a minimal element and \( y_h \) is a maximal element. Let \( m_1, m_2, \ldots, m_t \) be the maximal chains in \( P \) which contain \( c \cup d \), and assume that they are listed in the order in which they appear in the strong shelling order \( > \) of \( P \). Denote \((m_i \setminus (c \cup d)) \cup \{x, y\}\) by \( \tilde{m}_i \).

For each \( i \) and \( j \) with \( 1 \leq i < j \leq t \), by the strong shellability of \( \Delta(P) \), we can find \( m > m_j \) with \( \text{dis}(m, m_j) = 1 \) and \( \text{dis}(m, m_i) = \text{dis}(m_i, m_j) - 1 \) by Lemma 4.2. With the help of Lemma 4.1, we have \( c \cup d \subseteq m \). Thus, \( m = m_k \) for some \( k \). As \( m_k > m_j \), we have \( k < j \). Now, it is straightforward to verify that \( \text{dis}(\tilde{m}_k, \tilde{m}_j) = 1 \) and \( \text{dis}(\tilde{m}_k, \tilde{m}_i) = \text{dis}(\tilde{m}_j, \tilde{m}_i) - 1 \). Therefore, \( \tilde{m}_1, \ldots, \tilde{m}_t \) is a strong shelling order of the interval \([x, y]\). \( \square \)

Let \( P \) and \( Q \) be two posets. The **ordinal sum** \( P \oplus Q \) is the poset on the disjoint union of \( P \) and \( Q \) defined by the rule: \( x \leq y \) in \( P \oplus Q \) if and only if (i) \( x, y \in P \) and \( x \leq y \) in \( P \), or (ii) \( x, y \in Q \) and \( x \leq y \) in \( Q \), or (iii) \( x \in P \) and \( y \in Q \). Like [2, Theorem 4.4], we have

**Proposition 5.3.** Let \( P \) and \( Q \) be two finite posets. Then the ordinal sum \( P \oplus Q \) is strongly shellable if and only if both \( P \) and \( Q \) are strongly shellable.

**Proof.** The order complexes satisfy \( \Delta(P \oplus Q) = \Delta(P) \ast \Delta(Q) \). Thus, we can apply Proposition 2.16. \( \square \)

However, other poset constructions, like direct product, cardinal power, interval poset, are easily seen to be not compatible with strong shellability.

### 6. Relations with other shellable conditions

In this section, we will show some relations among the concepts related to shellability. First, recall the following two conditions:

**Definition 6.1.**

(a) A **matroid complex** \( \Delta \) is a simplicial complex with the exchange property: for any two distinct facets \( F, G \subseteq \mathcal{F}(\Delta) \) and for any \( i \in F \setminus G \), there exists some \( j \in G \setminus F \) such that \((F \setminus \{i\}) \cup \{j\} \in \Delta \). Alternatively, \( \Delta \) is called a **matroid complex** if for every subset \( W \subseteq \mathcal{V}(\Delta) \), the induced subcomplex \( \Delta_W \) is pure. For other equivalent characterizations, see, for instance, [16, Proposition III.3.1].

(b) A **shifted complex** \( \Delta \) on \([n]\) is a simplicial complex such that for each \( F \in \Delta \), if \( i \in F \) and \( j \in [n] \) with \( j > i \), then \((F \setminus \{i\}) \cup \{j\} \in \Delta \).

**Example 6.2.** Let \( \Delta \) be the nonpure simplicial complex with the facet set \( \mathcal{F}(\Delta) \):
\[
\{\{1, 2\}, \{1, 3, 6\}, \{1, 4, 6\}, \{1, 5, 6\}, \{2, 3, 6\}, \{2, 4, 6\}, \{2, 5, 6\}, \{3, 4, 5\}, \{3, 4, 6\}, \{3, 5, 6\}, \{4, 5, 6\}\}
\]
One can check directly that \( \Delta \) is shifted. On the other hand, this simplicial complex is not strongly shellable; it suffices to compare the two facets \( \{1, 2\} \) and \( \{3, 4, 5\} \).

Note that any matroid complex is pure, and as the above example shows, a nonpure complex needs not to be strongly shellable, even though it is shifted. Thus, in this section, we are mainly concerned with pure complexes.
Proposition 6.3. Matroid complexes are strongly shellable.

Proof. Let $\Delta$ be a matroid complex defined on the set $[n]$. We will prove that $\Delta$ is strongly shellable by induction on $n$. Without loss of generality, we may assume that the vertex $n$ appears in some but not all facets of $\Delta$. Now, $\Delta \setminus n$ and $\text{link}_\Delta(n)$ are matroid complexes on the set $[n-1]$ with dimension $\dim(\Delta)$ and $\dim(\Delta) - 1$ respectively. By inductive assumption, both $\Delta \setminus n$ and $\text{link}_\Delta(n)$ are strongly shellable. Assume that $F_1, \ldots, F_s$ and $G_1, \ldots, G_t$ are strong shelling orders on $\mathcal{F}(\Delta \setminus n)$ and $\mathcal{F}(\text{link}_\Delta(n))$ respectively. We claim that

$$\triangleright: \ F_1, \ldots, F_s, G_1 \cup \{n\}, \ldots, G_t \cup \{n\}$$

is a strong shelling order on $\mathcal{F}(\Delta)$. It suffices to compare the pair $F_a \triangleright G_b \cup \{n\}$, where $1 \leq a \leq s$ and $1 \leq b \leq t$. Since $\Delta$ is a matroid complex and $n \in (G_b \cup \{n\}) \setminus F_a$, we can find some $m \in F_a \setminus (G_b \cup \{n\})$ such that $((G_b \cup \{n\}) \setminus \{n\}) \cup \{m\} = G_b \cup \{m\} \in \Delta$. Thus, $G_b \cup \{m\} \in \Delta \setminus n$ which means that $G_b \cup \{m\} = F_c$ for some $1 \leq c \leq s$. Obviously, $F_c \triangleright G_b \cup \{n\}$.

The proof of the above proposition also shows that, for a matroid complex, the reverse lexicographic order on the facet set gives a strong shelling order.

Example 6.4. In [1], the authors investigated the spanning tree complex of a connected graph. More generally, one can consider the spanning forests of a not necessarily connected graph $G$. A subset $F \subseteq \mathcal{E}(G)$ is called a spanning forest if for each connected component $L$ of $G$, $L \cap F$ is a spanning tree of $L$. We will write $s(G)$ for the set of spanning forests of $G$. The spanning forest complex $\Delta_S(G)$ of $G$ will be the unique complex over $\mathcal{E}(G)$, whose facet set is $s(G)$. It is not difficult to see that $\Delta_S(G)$ is a matroid complex, which is known as the cycle matroid of the graph $G$; see, for instance, [14]. Indeed, if $G_1, \ldots, G_s$ are the connected components of $G$, then

$$\Delta_S(G) \cong \Delta_S(G_1) \ast \cdots \ast \Delta_S(G_s),$$

the join of matroid complexes, hence again a matroid complex. In particular, by 6.3, $\Delta_S(G)$ is strongly shellable.

To be more specific, if $|\mathcal{E}(G)| = n$ and we label the edges of $G$ arbitrarily by distinct integers in $[n]$, the reverse lexicographic order on the sets of labels of the spanning forest gives rise to a strong shelling order. For instance, one can consider the simple graph $G$ of Figure 5a with the given labels. List all spanning trees by reverse lexicographic order on the labels:

$$124, 134, 234, 125, 135, 235, 145, 245.$$ 

This order is a strong shelling order on the facet set of the spanning forest complex $\Delta_S(G)$. The codimension one graph of $\Delta_S(G)$ is pictured in Figure 5b.

Proposition 6.5. Pure shifted complexes are strongly shellable.

Proof. Let $\Delta$ be a pure shifted complex on the vertex set $[n]$. We will show that $\Delta$ is strongly shellable by induction on the cardinality of the vertex set. Assume that the result holds for the case of $n - 1$. Without loss of generality, we may assume that the vertex $1$ appears in some but not all facets of $\Delta$. Note that $\Delta \setminus 1$ and $\text{link}_\Delta(1)$ are pure shifted complexes on the vertex set $\{2, 3, \ldots, n\}$ of dimension $\dim(\Delta)$ and $\dim(\Delta) - 1$ respectively. Thus, by inductive assumption, we can find strong shelling orders $F_1, \ldots, F_p$ and $E_1, \ldots, E_q$ for $\mathcal{F}(\Delta \setminus 1)$ and $\mathcal{F}(\text{link}_\Delta(1))$ respectively. We claim that

$$\triangleright: \ F_1, \ldots, F_p, E_1 \cup \{1\}, \ldots, E_q \cup \{1\}$$

is a strong shelling order on $\mathcal{F}(\Delta)$. It suffices to compare the pair $F_a \triangleright E_b \cup \{1\}$, where $1 \leq a \leq p$ and $1 \leq b \leq q$. Since $\Delta$ is a pure shifted complex and $E_b \cup \{1\} \subsetneq (\Delta \setminus 1) \setminus F_a$, we can find some $m \in (\Delta \setminus 1) \setminus (E_b \cup \{1\})$ such that $((E_b \cup \{1\}) \setminus \{1\}) \cup \{m\} = E_b \cup \{m\} \in \Delta$. Thus, $E_b \cup \{m\} \in \Delta \setminus 1$ which means that $E_b \cup \{m\} = F_c$ for some $1 \leq c \leq q$. Obviously, $F_c \triangleright E_b \cup \{1\}$.
is a strong shelling order on $\mathcal{F}(\Delta)$. In fact, for $F_i > E_j \cup \{1\}$ in $\mathcal{F}(\Delta)$, there exists an integer $t \in F_i \setminus (E_j \cup \{1\})$. Since $\Delta$ is shifted, $E_j \cup \{t\} \in \mathcal{F}(\Delta)$. Obviously, $E_j \cup \{t\} \in \mathcal{F}(\Delta \setminus 1)$ which means $E_j \cup \{t\} = F_k$ for some $1 \leq k \leq p$. Of course, $F_k > E_j \cup \{1\}$. It is also easy to see that $\text{dis}(E_j \cup \{t\}, E_j \cup \{1\}) = 1$ and $\text{dis}(F_i, E_j \cup \{t\}) = \text{dis}(F_i, E_j \cup \{1\}) - 1$. This completes the proof.

The proof of the above proposition also shows that, for a pure shifted complex, if $L_1, \ldots, L_s$ is a linear order on the facet set given by the lexicographic order, then $L_s, \ldots, L_1$ is a strong shelling order.

Recall that a $d$-dimensional pure complex $\Delta$ is \textit{vertex decomposable} if either $\Delta$ is a $d$-simplex, or there exists a vertex $x$ of $\Delta$ (called a \textit{shedding vertex}), so that

(i) $\Delta \setminus x$ is pure of dimension $d$ and vertex decomposable, and

(ii) $\text{link}_\Delta(x)$ is pure of dimension $d - 1$ and vertex decomposable.

This definition was introduced by Provan and Billera [15, Definition 2.1]. For the nonpure version, see [4, Definition 11.1]. It is not difficult to see that matroid complexes are pure vertex decomposable, see [15, Theorem 3.2.1]. It was also shown in [4] that for nonpure complexes, we have

\[ \text{shifted} \implies \text{vertex decomposable} \implies \text{shellable}. \]

Recall that Kokubo and Hibi [9] introduced the weakly polymatroidal ideals. We will consider the Eagon complexes of squarefree weakly polymatroidal ideals. To be more precise,

\textbf{Definition 6.6.} A simplicial complex $\Delta$ on the vertex set $[n]$ is called a \textit{weakly matroid complex}, if for each distinct facets $G$ and $F$, with respect to the unique vertex $q \in G \setminus F$ such that for each $i < q$, $i \in F$ if and only if $i \in G$, there exists some $p \notin G$ with $q < p \leq n$ such that $(\{p\} \cup G \setminus \{q\}) \in \Delta$.

It is immediate that shifted complexes and matroid complexes are weakly matroidal. On the other hand, by [11, Theorem 2.5], weakly matroid complexes are vertex decomposable.

In [7], Hachimori and Kashiwabara introduced hereditary-shellable complexes. According to them, a complex is called \textit{hereditary-shellable} if all its restrictions are (nonpure) shellable. For pure complexes, they [8] established the relations

\[ \text{hereditary-shellable} \implies \text{matroid} \implies \text{vertex decomposable} \implies \text{shellable}. \]
It is easy to find a pure vertex decomposable complex which is not hereditary-shellable. On the other hand, [8, Example 4.6] shows a pure hereditary-shellable complex which is not vertex decomposable.

In the following, we will give additional examples which show that there is no implication between strong shellability with hereditary-shellability or vertex decomposability.

**Example 6.7** (Strongly shellable, but not vertex decomposable). We have already mentioned that [8, Example 4.6] gives a pure complex which is hereditary-shellable but not vertex decomposable. Actually, one can check directly that it is also strongly shellable. The facet set of this complex has the following strong shelling order:

\[
\{a_1, b_1, c_1\}, \{a_1, b_1, c_2\}, \{a_1, b_1, c_3\}, \{a_1, b_1, c_4\}, \{a_1, b_2, c_1\}, \{a_1, b_2, c_2\}, \\
\{a_1, b_2, c_3\}, \{a_1, b_2, c_4\}, \{a_1, b_3, c_1\}, \{a_1, b_3, c_2\}, \{a_1, b_3, c_3\}, \{a_1, b_3, c_4\}, \\
\{a_2, b_1, c_1\}, \{a_2, b_1, c_2\}, \{a_2, b_1, c_3\}, \{a_2, b_1, c_4\}, \{a_2, b_2, c_1\}, \{a_2, b_2, c_2\}, \\
\{a_2, b_2, c_3\}, \{a_2, b_2, c_4\}, \{a_2, b_3, c_1\}, \{a_2, b_3, c_2\}, \{a_2, b_3, c_3\}, \{a_2, b_3, c_4\}, \\
\{a_2, b_4, c_1\}, \{a_2, b_4, c_2\}, \{a_2, b_4, c_3\}, \{a_2, b_4, c_4\}, \{a_3, b_1, c_1\}, \{a_3, b_1, c_2\}, \\
\{a_3, b_2, c_1\}, \{a_3, b_2, c_2\}, \{a_3, b_2, c_3\}, \{a_3, b_2, c_4\}, \{a_3, b_3, c_1\}, \{a_3, b_3, c_2\}, \\
\{a_3, b_3, c_3\}, \{a_3, b_3, c_4\}, \{a_3, b_4, c_1\}, \{a_3, b_4, c_2\}, \{a_3, b_4, c_3\}, \{a_3, b_4, c_4\}, \\
\{a_4, b_1, c_1\}, \{a_4, b_1, c_2\}, \{a_4, b_1, c_3\}, \{a_4, b_1, c_4\}, \{a_4, b_2, c_1\}, \{a_4, b_2, c_2\}, \\
\{a_4, b_2, c_3\}, \{a_4, b_2, c_4\}, \{a_4, b_3, c_1\}, \{a_4, b_3, c_2\}, \{a_4, b_3, c_3\}, \{a_4, b_3, c_4\}, \\
\{a_4, b_4, c_1\}, \{a_4, b_4, c_2\}, \{a_4, b_4, c_3\}, \{a_4, b_4, c_4\}, \{a_5, b_1, c_1\}, \{a_5, b_1, c_2\}, \\
\{a_5, b_2, c_1\}, \{a_5, b_2, c_2\}, \{a_5, b_3, c_1\}, \{a_5, b_3, c_2\}, \{a_5, b_4, c_1\}, \{a_5, b_4, c_2\}, \\
\{a_6, b_1, c_1\}, \{a_6, b_1, c_2\}, \{a_6, b_1, c_3\}, \{a_6, b_1, c_4\}, \{a_6, b_2, c_1\}, \{a_6, b_2, c_2\}, \\
\{a_6, b_2, c_3\}, \{a_6, b_2, c_4\}, \{a_6, b_3, c_1\}, \{a_6, b_3, c_2\}, \{a_6, b_3, c_3\}, \{a_6, b_3, c_4\}, \\
\{a_6, b_4, c_1\}, \{a_6, b_4, c_2\}, \{a_6, b_4, c_3\}, \{a_6, b_4, c_4\}, \{a_6, b_5, c_1\}, \{a_6, b_5, c_2\}, \\
\{a_6, b_5, c_3\}, \{a_6, b_5, c_4\}, \{a_6, b_6, c_1\}, \{a_6, b_6, c_2\}, \{a_6, b_6, c_3\}, \{a_6, b_6, c_4\}. \\
\]

Using the language in [8, Example 4.6], the above strong shelling order first starts with the matroidal part, and then proceeds by carefully arranging the 12 extra facets.

**Example 6.8** (Strongly shellable, but not hereditary-shellable). Let $\Delta$ be a pure complex with the facet set:

\[
\{ \{1, 2, 8\}, \{1, 2, 5\}, \{2, 5, 6\}, \{1, 2, 4\}, \{1, 2, 7\}, \{1, 3, 4\}, \{1, 2, 6\}, \{1, 2, 3\} \}. 
\]

It is direct to check that $\Delta$ is strongly shellable with respect to the above given order. On the other hand, the restriction of $\Delta$ to the subset $W = \{3, 4, 5, 6, 7, 8\} \subseteq V(\Delta)$ has facets $\{3, 4\}, \{5, 6\}, \{7\}, \{8\}$. Obviously, $\Delta_W$ is not shellable. Therefore, the original complex $\Delta$ is not hereditary-shellable.

**Example 6.9** (Hereditary-shellable, weakly matroid, but not strongly shellable). Let $\Delta$ be a pure complex with the facet set:

\[
\{ \{1, 2, 6\}, \{1, 3, 4\}, \{1, 4, 6\}, \{2, 3, 5\}, \{2, 5, 6\}, \{3, 4, 5\}, \{3, 4, 6\}, \{3, 5, 6\} \}. 
\]

It is direct to check that $\Delta$ is hereditary-shellable and weakly matroid, but not strongly shellable.

**Proposition 6.10.** Shifted complexes are hereditary-shellable.

**Proof.** It suffices to note that for a shifted complex, any restriction is also shifted. \qed

Combining the concepts of hereditary-shellable and strongly shellable, we have the following natural definition.

**Definition 6.11.** A complex is called *hereditarily strongly shellable* if all its restrictions are strongly shellable.
Clearly, we have the following implications:

matroid $\longrightarrow$ hereditarily strongly shellable $\longrightarrow$ strongly shellable

The implications are strict.

Example 6.12. Let $\Delta$ be the pure complex with facets:

\{1, 2, 3\}, \{1, 2, 4\}, \{1, 2, 5\}, \{1, 2, 6\}, \{1, 3, 4\}, \{1, 3, 5\}, \{1, 3, 6\}, \{2, 4, 5\}.

One can check that $\Delta$ is hereditarily strongly shellable. On the other hand, the restriction of $\Delta$ to the subset $W = \{4, 5, 6\} \subseteq \mathcal{V}(\Delta)$ has facets $\{4, 5\}$ and $\{6\}$. Therefore, the induced complex $\Delta_W$ is not pure and the original complex $\Delta$ is not a matroid complex.

The implications among pure shellable complexes that we encountered in this section are summarized in Figure 6.

7. Deciding Strong Shellability of Pure Complexes with $h$-Assignments

In this final section, we briefly talk about how to decide the strong shellability of a pure complex. In [12] Moriyama considered a similar question for deciding the shellability of pure complexes.

Let $\Delta$ be a $d$-dimensional pure complex with $h$-vector

$$h(\Delta) = (h_0(\Delta), \ldots, h_{d+1}(\Delta)) \in \mathbb{N}^{d+2}.$$ 

In $\Delta$, a $(d-1)$-dimensional face is called a ridge of $\Delta$. A ridge contained in only one facet will be called a boundary ridge.

An $h$-assignment $A$ of $\Delta$ is a assignment $A : \mathcal{F}(\Delta) \to [d + 1]$ such that $|A^{-1}(i)| = h_i(\Delta)$ for each $i$. With respect to this $h$-assignment, a facet $F$ of $\Delta$ is called a candidate facet if $F$ contains exactly $d + 1 - A(F)$ boundary ridges of $\Delta$.

Given a candidate facet $F$ of $\Delta$ with respect to the $h$-assignment, we can apply a removing step by

(i) replacing $\Delta$ by $\Delta' = \langle G \in \mathcal{F}(\Delta) : G \neq F \rangle$, and
(ii) replacing $A$ by the its restriction on $\mathcal{F}(\Delta')$.

Theorem 7.1 ([12, Theorem 1.3]). A pure complex $\Delta$ is shellable if and only if there exists an $h$-assignment such that we can remove all facets of $\Delta$ by applying the removing steps successively.
From its proof, we know that given a shelling order of $\Delta$, one has a natural $h$-assignment in which the last facet of the shelling will be a candidate facet. Conversely, given an $h$-assignment which allows the removing steps above, we can build a shelling order by reversing the removal order.

Given an $h$-assignment, a candidate facet $F$ is called a strong candidate facet if for each $G \neq F$, there exists a facet $H$ such that $\text{dis}(F, H) = 1$ and $\text{dis}(G, H) = \text{dis}(G, F) - 1$.

It follows immediately from Lemma 4.2 and Theorem 7.1 that

**Theorem 7.2.** A pure complex $\Delta$ is strongly shellable if and only if there exists an $h$-assignment such that we can remove all facets of $\Delta$ by applying the removing steps successively such that we remove a strong candidate facet at each step.

The benefit of applying this deciding method is the same as that for Moriyama’s suggestion, namely, instead of checking all $|\mathcal{F}(\Delta)|!$ possible cases by definition, we only need to check, roughly speaking,

$$\frac{|\mathcal{F}(\Delta)|!}{h_0(\Delta)! \cdots h_{d+1}(\Delta)!}$$

possible cases. The last integer is the number of all $h$-assignments of $\Delta$.
